## MATH 110 Tutorial 10

Modular arithmetic can be thought of as doing calculations on **remainders** upon division by a given number.

We compute the (multiplicative) *inverse* of a modulo p by computing the extended Euclidean algorithm on a, p.

We can use the information of an inverse to solve a linear equation. Consider the equation  $ax = b \mod p$ . If a is non-zero modulo p, we can compute the inverse of a, and multiply both sides of the equation by  $a^{-1}$ :

$$a^{-1}(ax) = (a^{-1}a)x = x = a^{-1}b \mod p.$$

There is nothing special about our approach to a single linear equation; this works in general for a set of linear equations. Matrix calculations can be carried out modulo p.

## Practice Problems.

1. What is 1 + 2 + 3 + 4 + 5 modulo 2,3,5 ? What is  $2 \cdot 4 + 4 \cdot 7 + 5 \cdot 3$  modulo 2,3,19 ?

2. Compute the inverses of 3 mod 11, 8 mod 13, and 4 mod 7. Use your answers to solve the equations  $3x + 2 = 8 \mod 11$ ,  $8x - 3 = 6 \mod 13$ ,  $4x = 0 \mod 7$ .

3. Determine the complete solution set for the following systems of equations.

4. Challenge. For what values of a does ax = 1 have a solution modulo 4?
